

## Problem I. Ivan Smirnov

Input file: *standard input*  
Output file: *standard output*  
Time limit: 2 seconds  
Memory limit: 512 mebibytes

<https://stackoverflow.com/questions/45658828/number-of-ways-to-merge-2-parenthesis-sequences>. Now you can solve a strictly harder problem in about  $10^{18}$  years. This almost fits in the time limit. All you have to do is some minor optimizations.

Two sequences of parentheses  $s$  and  $t$  **mergeable** if they can be interleaved to form a balanced parentheses sequence. Formally, if  $s$  has length  $n$  and  $t$  has length  $m$  they are mergeable if and only if there exists a balanced parentheses sequence  $p$  of length  $n+m$ , and two disjoint sequences of indices  $a$  and  $b$  of length  $n$  and  $m$  respectively, such that:

1.  $0 \leq a_1 < a_2 < \dots < a_n < n + m$
2.  $0 \leq b_1 < b_2 < \dots < b_m < n + m$
3. For all  $i$   $p_{a_i} = s_i$
4. For all  $i$   $p_{b_i} = t_i$

The **RLE** (Run Length Encoding) of some string is a list of pairs  $(c_i, a_i)$  where  $c_i$  is a character and  $a_i$  is a positive integer and  $\forall_i c_i \neq c_{i+1}$ , the length of the encoding (i.e. number of pairs in the list) is called the **run length** of the string. The original string of RLE  $[(c_1, a_1), (c_2, a_2), \dots, (c_n, a_n)]$  consists of  $a_1$  repetitions of character  $c_1$ , followed by  $a_2$  repetitions of character  $c_2$ , and so on, and ends with  $a_n$  repetitions of character  $c_n$ . It can be shown that RLE is unique.

You are given an RLE of a parentheses sequence  $s$  and RLEs of  $m$  other parentheses sequences candidates  $t_i$ . For each  $i$  find out if  $t_i$  and  $s$  are mergeable.

### Input

The input starts with a description of the sequence  $s$ . The first line contains a single integer  $n$  ( $1 \leq n \leq 3 \cdot 10^5$ ), the run length of  $s$ .

$n$  lines follow.  $i$ -th of them describes a single pair in the RLE of  $s$  and contains a character  $c_i$  and an integer  $a_i$  separated by a single space ( $c_i \in \{(\,)\}, c_i \neq c_{i+1}, 1 \leq a_i \leq 10^{12}$ ).

The next line contains a single integer  $m$  ( $1 \leq m \leq 3 \cdot 10^5$ ), the number of sequences  $t$  to check.

The remaining lines describe those sequences one by one, using the same format as the description of  $s$ . If this isn't clear you should take a look at the samples.

It is guaranteed that the sum of run lengths of those  $m$  sequences doesn't exceed  $3 \cdot 10^5$ .

### Output

Print  $m$  lines.

The  $i$ -th of those lines should contain 1 if  $t_i$  and  $s$  are mergeable and 0 if they are not.

## Examples

standard input	standard output
<pre>4 ( 1 ) 3 ( 3 ) 1 1 2 ( 1 ) 1</pre>	<pre>0</pre>
<pre>2 ( 2 ) 1 4 1 ( 1 1 ) 1 2 ) 2 ( 1 2 ) 4 ( 3</pre>	<pre>0 1 1 0</pre>
<pre>4 ) 2 ( 3 ) 5 ( 100 3 1 ) 96 2 ( 132 ) 228 4 ( 2 ) 3 ( 5 ) 100</pre>	<pre>0 1 1</pre>
<pre>1 ) 1000000000000 2 1 ) 1000000000000 1 ( 1000000000000</pre>	<pre>0 1</pre>
